ABSTRACT

IC 2391 and IC 2602 are important benchmarks for testing early star and planet evolution theories, both structural and dynamical, because they are the nearest open clusters with ages of \sim 50 Myr. We refine membership lists for these clusters by identifying candidate members using Gaia DR2 kinematic and distance information. We identify 451 candidate members of IC 2602 and 350 candidate members of IC 2391. If confirmed, this would increase the known populations of these clusters by 275% and 130% respectively. We use CHIRON on the CTIO/SMARTS 1.5-m telescope via fiber mode which yields a resolution of 27,400 to acquire high resolution spectra of 26 new candidate cluster members brighter than G=13 magnitude, as well as an additional 12 previously known members. Measures of lithium, $H\alpha$, stellar properties (Teff, log(g), [Fe/H]), radial velocities, and $v \sin i$ values from these spectra are used to confirm cluster membership. We find that 37 of 38 stars we observe are bona-fide cluster members, of which 4 are new candidate photometric binaries and 10 are new candidate spectroscopic binaries.

Keywords: Hertzsprung-Russell and C-M diagrams — open clusters and associations: general — open clusters and associations: individual (IC 2602, IC 2391) — stars: fundamental parameters — stars: kinematics and dynamics)

1. INTRODUCTION

IC 2602 and IC 2391 are nearby (~150 pc; Bravi et al. 2018) open clusters located in the Carina and Vela constellations respectively. Despite being spatially close on the sky (within 30 degrees), the clusters differ in their space motions and likely do not share a common origin; the mean radial velocities of IC 2602 and IC 2391 are estimated to be 17.4±1.0 km/s (Marsden et al. 2009) and 14.8±0.7 km/s (Platais et al. 2007) respectively. It is believed that IC 2602 formed in conjunction with the Local association, otherwise known as the Pleaides supercluster (Eggen 1975, 1983a,b), while IC 2391 formed alongside the Argus association (Torres et al. 2008, De Silva et al. 2013) as part of the IC 2391 supercluster

er 51 e 52 n 53 t

40 and 0.088±0.027 respectively.
41 Spectra of their main-sequence FGK stars reveal that
42 IC 2602 and IC 2391 have near-solar metallicities of
43 0.00±0.01 and 0.06±0.06 respectively (Randich et al.
44 2001, 2002; Platais et al. 2007; D'Orazi & Randich 2009;
45 Marsden et al. 2009; Boudreault & Bailer-Jones 2009;
46 Spina et al. 2017). Age estimates for IC 2602 and IC
47 2391 are determined to be 43.7^{+4.3}_{-3.9} and 51.3^{+5.0}_{-4.5} Myr
48 respectively, which are inferred by modeling the lithium
49 depletion boundary and chasm (Barrado y Navascués et
50 al. 2004; Dobbie et al. 2010; Bravi et al. 2018). The age
51 estimates are consistent with those determined from the
52 main sequence turnoff (~30-50 Myr), which is poten53 tially plagued by rapid rotation and gravity darkening
54 (Jones et al. 2015; Brandt & Huang 2015; Cummings et

55 al. 2017; Randich et al. 2018).

 $_{38}$ (Eggen 1991). IC 2602 and IC 2391 experience low reddening with estimated E(B-V) values of 0.068 ± 0.025

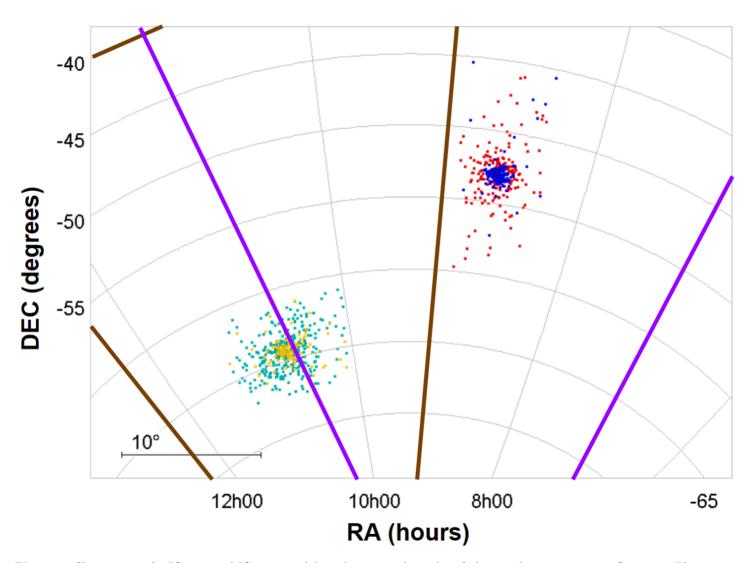

Figure 1. Sky positions for IC 2602 and IC 2391 candidate cluster members identified using the prescription in Section 2. The RA and DEC ranges of search regions are shown and extend off the plot (brown for IC 2602 and purple for IC 2391). New and known IC 2391 candidate members are represented by red and blue points, respectively. New and known IC 2602 candidate members are represented by cyan and yellow points, respectively.

Given their close proximity and age, IC 2602 and IC 2391 are important benchmark clusters because they are the closest clusters with ages intermediate between that of star forming regions (< 10 Myr) and that of well-studied open clusters (> 100 Myr; Lada & Lada 2003). At these transitional ages, low mass stars are still gravitationally settling towards the main sequence (Baraffe et al. 2015) and planetary systems are in the process of dynamically evolving (Quinn & White 2016; Mann et al. 2017; Gaidos et al. 2017; Ragusa et al. 2018).

To study these clusters in detail, a plethora of in-67 vestigations have been undertaken to identify poten-68 tial candidate members of IC 2602 and IC 2391 via 69 parallax, proper motion, spatial extent, and photome-70 try (Whiteoak 1961; Feinstein 1961; Braes 1962; Lyngå 71 1962; Foster et al. 1997; Rolleston & Byrne 1997; Simon 72 & Patten 1998; Barrado y Navascués et al. 2001; Dodd 73 2004; Randich et al. 2005; Gagné et al. 2018). Addi-74 tionally, numerous spectroscopic studies have been con-75 ducted to confirm candidate members via signatures of ₇₆ youth (e.g. lithium, $H\alpha$, large $v \sin i$) and stellar prop-77 erties consistent with those of bona-fide cluster mem-78 bers (Buscombe 1965; Abt & Morgan 1972; Levato et 79 al. 1988; Messina et al. 2003; Paulson & Yelda 2006; 80 Platais et al. 2007; Mermilliod et al. 2009; De Silva et 81 al. 2013; Merle et al. 2017; D'Orazi et al. 2017). Both 82 clusters appear to harbor a population of brown dwarfs 83 (Barrado y Navascués et al. 2004; Dobbie et al. 2010).

The European Space Agency's *Gaia* satellite has revolutionized our capacity to recognize and characterize
Galactic star clusters and has the potential to significantly refine membership lists for open clusters (CantatGaudin et al. 2018; Lodieu et al. 2019; Zuckerman et al.
Discription is largely successful in identifying candidate
cluster members (Gaia Collaboration et al. 2018), the
prescription is still known to miss bona-fide members in
some instances (Zuckerman et al. 2019). Furthermore,
stars retrieved from *Gaia* are still only candidate members until confirmed with spectra because even the best
samples are affected by contamination from field stars
(Briceno et al. 2018).

In the current work, we utilize the second data release (Gaia DR2; Gaia Collaboration et al. 2018), which provides kinematic and distance information for over 1 billion stars, to identify potential candidate members of IC 2602 and IC 2391 (Section 2). We obtain high-dispersion optical spectra for all newly identified candidate members of IC 2602 and IC 2391 brighter than G=13 magnitude (Section 3). We use the spectra to measure youth diagnostics, radial and projected rotational velocities, as well as determine stellar properties for each star (Section

 Table 1. Properties of Candidate Cluster Members

Cluster	Property	Constraint
IC 2602	RA (hr)	$10 \le RA \le 11.3$
	DEC (deg)	$-67.5 \le DEC \le -61$
	$\boldsymbol{\varpi} \; (\mathrm{mas})$	$6.2 \le \varpi \le 7.0$
	$\mu_{\alpha}\cos\delta$ (mas/yr)	$-25 \le \mu_{\alpha} \cos \delta \le -10$
	$\mu_{\delta} \; (\text{mas/yr})$	$6 \le \mu_{\delta} \le 17$
	ϵ_{ϖ} (mas)	$\epsilon_{\varpi} \le 0.5 \text{ (if G } \le 8)$
		$\epsilon_{\varpi} \le 0.35 \text{ (if G > 8)}$
	$\epsilon_{\mu_{\alpha}\cos\delta}$ (mas/yr)	$\epsilon_{\mu_{\alpha}\cos\delta} \le 0.8$
	$\epsilon_{\mu_{\delta}} \; (\text{mas/yr})$	$\epsilon_{\mu_{\delta}} \le 0.8$
$IC\ 2391$	RA (hr)	$8.3 \le RA \le 9$
	DEC (deg)	$-60 \le DEC \le -45$
	$\boldsymbol{\varpi} \; (\mathrm{mas})$	$6.2 \le \varpi \le 7.4$
	$\mu_{\alpha}\cos\delta$ (mas/yr)	$-31 \leq \mu_{\alpha} \cos \delta \leq -19$
	$\mu_{\delta} \; (\text{mas/yr})$	$15 \le \mu_{\delta} \le 28$
	ϵ_{ϖ} (mas)	$\epsilon_{\varpi} \le 0.5 \text{ (if G } \le 8)$
		$\epsilon_{\varpi} \le 0.35 \text{ (if G > 8)}$
	$\epsilon_{\mu_{\alpha}\cos\delta}$ (mas/yr)	$\epsilon_{\mu_{\alpha}\cos\delta} \le 0.8$
	$\epsilon_{\mu_{\delta}} \; (\text{mas/yr})$	$\epsilon_{\mu_{\delta}} \le 0.8$

Notes. Candidate cluster members are identified based on right-ascension (RA), declination (DEC), parallax (ϖ) , proper motion in right ascension $(\mu_{\alpha} \cos \delta)$, and proper motion in declination (μ_{δ}) , as well as uncertainties of parallax (ϵ_{ϖ}) and proper motion $(\epsilon_{\mu_{\alpha}} \cos \delta, \mu_{\delta})$.

108 3). These measurements allow us to identify new can109 didate binaries (Section 4), assess cluster membership
110 (Section 5), and characterize ensemble cluster proper111 ties (Section 6).

2. USING *GAIA* DR2 TO IDENTIFY CANDIDATE CLUSTER MEMBERS

We query the *Gaia* DR2 archive for candidate cluster members with declination and right ascension boundaries centered about the average SIMBAD coordinates (Wu et al. 2009) of bona-fide members (160°, -65° for IC 2602; 130°, -53° for IC 2391). The boundaries extend 25° in DEC and 1.7 hr in RA (Figure 1). Within these regions, we identify candidate cluster members using the constraints listed in Table 1 on parallax, proper motion, and measurement uncertainties. We apply a less strict parallax uncertainty constraint for stars brighter than G = 8 mag (0.5 vs. 0.35 mas), based on the recommendations of Drimmel et al. (2019); brighter stars have parallaxes with larger systematic errors.

4 Nisak et al.

This prescription identifies 451 candidate members of IC 2602, with G magnitudes spanning from 4.7 to 19.5. Likewise, it identifies 350 candidate members of IC 2391 with G magnitudes spanning from 3.5 to 19.6. These stars are plotted on color-magnitude diagrams in Figure 2.

Considering candidate members with G < 14, our

133

134 membership lists agree with those of the Gaia collaboration (Gaia Collaboration et al. 2018) to 90% (96 stars) 136 and 95% (78 stars) for IC 2602 and IC 2391, respectively. 137 Over the full magnitude range, our prescription yields 138 46 and 54 candidate members of IC 2602 and IC 2391, 139 respectively, that are not present in the Gaia Collabora-140 tion's membership lists. For G < 14, we identify 13 and candidate members of IC 2602 and IC 2391, respec-142 tively, are identified by the Gaia Collaboration, but not by the prescription used in this work. While the single-144 star main sequences are well-defined for these populations overall, they broaden for G > 15 due to larger 146 distance errors; median parallax uncertainties for both 147 clusters are 0.03 mas (G<15), 0.07 mas (15<G<17), and $_{148}$ 0.12 mas (17<G; Gaia Collaboration et al. 2018). To determine which of our candidate members are 149 known members of these clusters independent of those proposed by the Gaia Collaboration, we conduct a cross-152 match with SIMBAD (Wenger et al. 2000) through Vizier's X-Match (Ochsenbein et al. 2000) within a 1 154 arc-second radius of the Gaia DR2 coordinates. A can-155 didate member is considered to be a known member if (1) the star is present in SIMBAD and (2) the star has been previously classified as a candidate member of the 158 cluster. From this, we determine that our membership 159 lists contain 120 known members and 331 new candidate 160 members for IC 2602, and 152 known members and 198 161 new candidate members for IC 2391 (see Figure 2 and 162 3). If these new candidate members are confirmed, the 163 known stellar populations of these clusters will increase by 275% and 130% respectively.

Renormalized unit weight error (RUWE) values are used in some papers to assess membership of canditate cluster members (Lindegren et al. 2018; Esplin & Luhman 2019; Luhman & Esplin 2020). We don't use RUWE constraints because bright stars and photometric binaries are preferentially excluded. Bright stars are lost because they have large systematic errors in Gaia DR2 astrometry (Drimmel et al. 2019) while photometric binaries are lost because the astrometric χ^2 relies on a single-star model.

Our new refined membership lists can be found in Appendix tables A.1 (for IC 2391) and A.2 (for IC 2602). The lists are sorted by *Gaia* BP-RP color. For some stars (4 in IC 2391 and 10 in IC 2602), BP-RP color was

 $_{179}$ not provided. Furthermore, the 3 stars with BP-RP < $_{180}$ 1 and G > 13 are unlikely to be white dwarfs based on $_{181}$ their ages. If the Gaia photometry is correct for these, $_{182}$ follow-up spectroscopy may confirm them to be back- $_{183}$ ground giants (Richer et al. 2021). Because these stars $_{184}$ still show similar distance and space motion as per our $_{185}$ prescription, we consider them to be candidate mem- $_{186}$ bers.

3. SPECTROSCOPIC OBSERVATIONS AND PROPERTIES OF CANDIDATE CLUSTER MEMBERS

187

188

189

212

223

To confirm the membership candidates identified here, 190 191 we initiate a spectroscopic survey project to acquire high 192 resolution spectra. We obtain spectra for all 26 bright 193 (G < 13) candidate members newly identified in this 194 study to confirm cluster membership. We also observe 195 12 previously known (also with G < 13) cluster mem-196 bers to check the reliability of our analysis techniques. 197 We obtain single-epoch 1200s exposures for each star 198 using the CHIRON echelle spectrograph (Tokovinin et 199 al. 2013; L. Paredes et al. 2021, in preparation) on 200 the CTIO/SMARTS 1.5-m telescope. The stars are ob-201 served in fiber mode, which covers 4500-8900 Å over 202 62 spectral orders at a resolving power of $R \sim 27,400$. 203 We also obtain a thorium-argon lamp spectrum be-204 fore each object spectrum for wavelength calibration. 205 The RECONS team at Georgia State University pro-206 cess the observed echelle spectra from CHIRON to pro-207 vide wavelength-calibrated spectral orders, as described 208 in Tokovinin et al. (2013). In order to measure radial 209 and projected rotational velocities, single-epoch spectra 210 of CHIRON standards¹ (A. Yep et al. in preparation) 211 are also obtained using the same spectral setup.

3.1. Li i $\lambda 6708 \text{ Å \& } H\alpha \text{ Equivalent Widths}$

As a first assessment of stellar youth, we measure equivalent widths of the lithium doublet at 6708 Å and the H α feature at 6563 Å using IRAF's Gaussian-fitting splot package. We estimate equivalent width uncertainties using the spectrograph pixel-wavelength scale p (0.097 Å at H α ; 0.100 Å at lithium), the measured Gaussian full-width at half maximum f of the spectral line, and the signal-to-noise ratio (SNR) per pixel, following the prescription of Cayrel (1988) and Deliyannis et al. 1993, 2019):

$$\Delta EW \simeq 1.5 \frac{\sqrt{fp}}{SNR}$$
 (1)

 $^{^1\} https://github.com/alexandrayep/CHIRON_Standards$

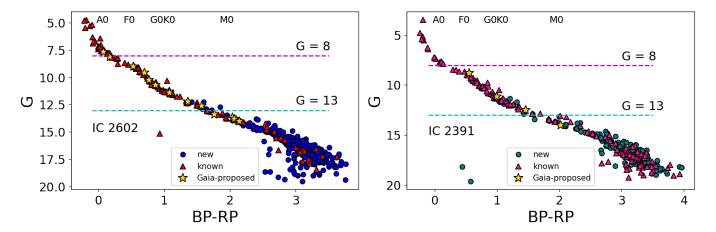

Figure 2. Gaia apparent G magnitude versus Gaia BP-RP color for 451 candidate members of IC 2602 (left panel) and 350 candidate members of IC 2391 (right panel); the 14 candidate members without Gaia colors (4 in IC 2391 and 10 in IC 2602) are not plotted. For IC 2602, 331 are new (blue circles) while 120 are known (red triangles). For IC 2391, 198 are new (teal circles) while 152 are known (pink triangles). Objects brighter than G=14 in the Gaia DR2 membership lists that are absent from ours are indicated by golden stars. The magenta line shows the brightness (G=8) above which a more lenient parallax constraint is applied in identifying membership (see Section 2). Estimated spectral types are shown at their corresponding Gaia color (Pecaut & Mamajek 2013). We obtain optical spectra for all new candidate members brighter than G=13 (see Section 3).

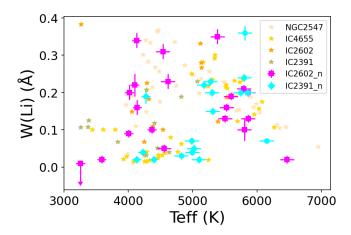

Figure 3. Equivalent widths of lithium at 6708 Å are plotted against effective temperatures (see Section 3.3) for all observed stars in this study for IC 2602 (magenta squares; IC2602_n) and IC 2391 (cyan circles; IC2391_n). Upper limits are indicated with arrows. Here, we show that our lithium measurements for IC 2602 and IC 2391 are consistent with those for other clusters of similar age (Gutiérrez Albarrán et al. 2020).

When reporting equivalent widths, we adopt the stan-224 dard convention of assigning negative values for emission 226 lines and positive values for absorption. Upper limits are assigned when the spectral line cannot be distin-228 guished from the noise of the continuum. For the can-229 didate double-lined spectroscopic binaries (see Section 230 4.2), equivalent widths are diminished due to the com-231 panion's continuum. The measured equivalent widths of 232 lithium absorption are plotted as a function of effective 233 temperature in Figure 3. The distributions of values are 234 consistent with measurements in clusters with similar age (30-50 Myr based on their main-sequence turnoffs) 236 from Gutiérrez Albarrán et al. (2020). Compared with 237 literature values in previously known members (as re-238 ported by Randich et al. 1997, 2001; Platais et al. 2007), 239 our measured values agree within measurement uncertainties (~ 0.02 Å). Equivalent width values are listed in Tables 3 and 4. New candidate members are designated ²⁴² with the internal identifiers ALN if they are in IC 2602 243 and NTC if they are in IC 2391.

3.2. Radial & Rotational Velocities

To measure the radial velocities (RV) and projected rotational velocities $(v \sin i)$ of target stars, we perform normalized cross-correlation of 12 spectral orders (4990-248 6860 Å). We avoid those with telluric absorption (e.g. 249 A-band, B-band), chromospheric emission (e.g. $H\alpha$), and pressure-sensitive lines that may bias the $v \sin i$ re-251 sults, between the target and three spectral standards 252 of similar Gaia BP-RP color.

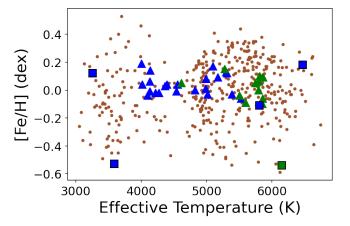

Figure 4. Metallicity is plotted against effective temperature for the 393 spectral standards (dwarf stars with $3 < \log(g) < 5$) used in the Empirical SpecMatch spectral library (red points). Previously known members and new candidate members observed in this study are colored green and blue, respectively. Stars are marked as squares if they are candidate double-lined spectroscopic binaries (see Section 4.2) and triangles if they are not.

A radial velocity is determined from each spectral order by fitting the peak of the cross-correlation function
(CCF) with a Gaussian. The radial velocity uncertainty
for each spectral order is estimated using the equation
from Butler et al. (1996). By weighing these relative radial velocities by their corresponding Doppler uncertainties, a weighted mean relative radial velocity is calculated. Barycentric velocities are determined using EXOFAST's (Eastman et al. 2013) barycentric correction algorithm (Wright & Eastman 2014) and PyAstronomy's
helcorr function.

We determine projected rotational velocities by creating an empirical relation between the CCF width and $v \sin i$, by cross-correlating each standard star spectrum against rotationally broadened synthetic versions of itself (using PyAstronomy's rotBroad function; Gray 1976, 1992; White et al. 2007). To obtain our final $v \sin i$ estimates, we average the $v \sin i$ measurements for all orders, taking the standard deviation of these as the uncertainty, and then calculate the weighted average of resulting $v \sin i$ estimates provided by 3 standard stars. We find that our measured radial and projected rotational velocities agree within 2 standard deviations of published literature values. Values are listed in Table 4.

3.3. Stellar Fundamental Parameters

277

We measure the stellar properties of the 38 observed stars using Empirical SpecMatch (Yee et al. 2017). This Python code determines stellar parameters of a spectrum by comparing it to a dense library of spectral stan-

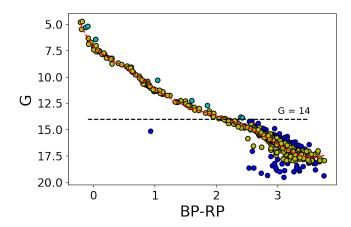

Figure 5. Candidate photometric binaries are identified in IC 2602 by an iterative fit to the main-sequence (down to G<18). Stars retained in the fit are shown as yellow circles. For stars brighter than G=14, any star more than 0.6 magnitudes above the fit are considered candidate binaries (cyan circles). For stars fainter than G=14 (blue circles), we do not identify binaries because of the broader main sequence.

when continuum normalization and $v\sin i$ provided by the SpecMatch program to float as free parameters, and (2) generating the best-matching linear combination of library spectra to determine stellar properties.

Figure 4 illustrates the best fit metallicities versus effective temperatures of candidate cluster members, along with the values of the comparison standards from which these values were determined. Stellar properties for the candidate double-lined spectroscopic binaries (including the two stars with [Fe/H]<-0.5) marked in Tables 3 and 4 are unreliable due to contamination of spectra by companions.

Using previously known members to test Empirical SpecMatch, we find that our derived properties for single star members are consistent to within the uncertainties of published literature values (Marsden et al. 2009; De Silva et al. 2013; Randich et al. 2018). Best fit effective temperatures, surface gravities, and metallicities for new and know members are listed in Tables 3 and 4, respectively.

4. NEW AND CANDIDATE BINARIES

We find new candidate photometric and spectroscopic binaries based on the following analyses.

4.1. New Candidate Photometric Binaries

308

Unresolved multiple star systems with companions of 310 comparable brightness are expected to be positioned 311 above the single star main sequence (Cantat-Gaudin et

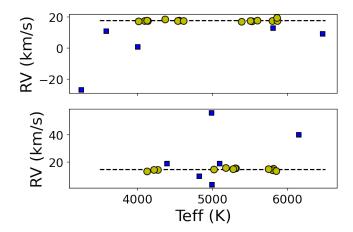

Figure 6. Distribution of RVs for spectroscopically observed stars in IC 2602 (top panel) and IC 2391 (bottom panel) as a function of effective temperature. Candidate binary stars (blue squares) are identified by iterative fits to the mean RVs (dotted black lines) of the ensembles; yellow circles are not candidate binaries.

³¹² al. 2018). To identify candidate photometric binaries, ³¹³ we use 8th-order polynomials to iteratively fit the main ³¹⁴ sequences for stars brighter than G=18 magnitude of ³¹⁵ these clusters. We classify candidate binary stars as ³¹⁶ those that sit above the fit by at least 0.6 magnitudes ³¹⁷ (see Figure 5); this is roughly 0.2 standard deviations ³¹⁸ above the best-fit main sequences. While we can be con-³¹⁹ fident this prescription works down to $G\sim14$, the pre-³²⁰ scription fails at dimmer magnitudes due to the spread ³²¹ in the main sequence. Considering only candidate mem-³²² bers with G<14, we identify 18 candidate photometric ³²³ binaries. We find that 14 of these are previously known ³²⁴ cluster members (7 in IC 2602 and 7 in IC 2391) while ³²⁵ 4 are new (2 in IC 2602 and 2 in IC 2391). Candidate ³²⁶ photometric binaries are marked in Tables 3 and 4.

4.2. New Candidate Spectroscopic Binaries

Cluster members with RVs significantly different from the mean RVs of cluster stars may be spectroscopic binaries (Platais et al. 2007). To identify such candidate spectroscopic binaries, we iteratively fit the mean RVs of cluster stars within 3 standard deviations. To obtain the best fit (see Figure 6), we regard as candidate spectroscopic binaries those stars with RVs different from the resulting means of the ensembles by more than 3 km/s (~1 standard deviation). Given that the internal radial velocity dispersions of these clusters is expected to be less than 1 km/s (Stauffer et al. 1997), we have applied a more stringent constraint for our 43-52 Myr clusters than the prescription used by Hayes & Friel (2014) for 1-3 Gyr clusters (3 km/s vs. 5 km/s). The stars we do not flag as candidate spectroscopic binaries are used to

 $_{343}$ estimate the cluster's radial velocities and dispersions in $_{344}$ Section 6.

Of the 11 new candidate spectroscopic binaries we identify (5 in IC 2602, 6 in IC 2391), we find that 5 are double-lined (4 in IC 2602, 1 in IC 2391) and 6 are single-lined (1 in IC 2602, 5 in IC 2391). These binaries are marked in Tables 3 and 4.

5. CONFIRMATION OF NEW CANDIDATE MEMBERS

350

378

We use the presence of lithium absorption or $H\alpha$ emis-352 353 sion to assign membership for candidate members. We 354 observe that 19 of 20 IC 2602 stars show lithium absorption while 12 of 20 show H α emission; 11 stars show both. Furthermore, we observe that all 18 IC 2391 stars show lithium absorption while 5 of 18 show H α emission. The double-lined spectroscopic binary, ALN 3, is the 358 359 star without detectable lithium absorption noted above. While ALN 3 shows $H\alpha$ emission, a known youth indicator in pre-main-sequence stars (Barrado Y Navascués et al. 2000; Casey et al. 2016; Gutiérrez Albarrán et al. 2020), such emission can also be produced by close-364 interacting field binaries (Vesper & Honeycutt 1993; Wevers et al. 2016). Since it is still possible that ALN 366 3 has weak lithium absorption diluted by the flux of a companion, we regard the membership of ALN 3 to IC 368 2602 to be uncertain.

Based on consistent distances, sky positions, proper motions, and the presence of lithium absorption or H α emission, we conclude that 19 of 20 IC 2602 and 18 IC 2391 candidate members are bona-fide cluster members. In combination with previously known members, 133 (29%) of IC 2602 and 164 (47%) of IC 2391 are spectroscopically confirmed members. Measurements are listed and binarity is indicated for these stars in Tables 3 and 377 4.

6. ENSEMBLE CLUSTER PROPERTIES

We use the newly assembled measurements to determine ensemble cluster properties for IC 2602 and IC 2391. Using kinematic candidate members we identify in Section 2 (451 stars in IC 2602, 350 stars in IC 2391), we stimate new mean right ascensions, declinations, parallaxes, and proper motions for cluster stars. We compute mean distances using the values calculated by Bailer-Jones et al. (2018). For completeness, we list cluster ages from Bravi et al. (2018).

For spectroscopically determined properties, candidate spectroscopic binaries are excluded from the average cluster RVs and double-lined binaries are excluded from the average metallicities (see Section 4.2). In total,

Table 2. Summary of Ensemble Cluster Properties

Property	Value	Std. Dev.
IC 2602		
Center RA (deg)	160.524 ± 0.004	$3.585(52\sigma_{mn})$
Center DEC (deg)	-64.387 ± 0.004	$1.231(18\sigma_{mn})$
Avg. $\boldsymbol{\varpi}$ (mas)	6.576 ± 0.004	$0.170(2.2\sigma_{mn})$

Notes. Ensemble cluster property values and uncertainties are listed in Column 2 while standard deviations are compared with mean individual uncertainties (σ_{mn}) in Column 3. Here, the reference B18 refers to Bravi et al. (2018).

mean RVs while 16 IC 2602 and 17 IC 2391 stars are used to estimate mean RVs while 16 IC 2602 and 17 IC 2391 stars are used to estimate mean metallicities. Our measured ensemble values agree with literature values to within the uncertainties of previous estimates (as reported by Randich et al. 2001; Platais et al. 2007; Marsden et al. 2009).

IC 2602 has central positions at RA= 160.524 ± 0.004 and DEC= -64.387 ± 0.004 degrees where errors represent uncertainties in the means. IC 2602 members have an average distance of 151.58 pc, with an uncertainty in the mean of ~1.8 pc and a standard deviation of 3.90 pc that is 2.1 times larger than the average distance uncertainty. IC 2602 members have a mean RV of 17.73 km/s with an uncertainty in the mean of 0.04 km/s and a standard deviation of 0.56 km/s that is 3.9 times larger than the average RV uncertainty.

IC 2391 has central positions at RA= 130.276 ± 0.005 and DEC= -52.923 ± 0.005 degrees where errors represent uncertainties in the means. IC 2391 members have an average distance of 150.44 pc, with an uncertainty in the mean of \sim 1.8 pc and a standard deviation of 4.99 pc that

 $_{413}$ is 2.7 times larger than the average distance uncertainty. $_{414}$ IC 2391 members have a mean RV of 14.88 km/s with $_{415}$ an uncertainty in the mean of 0.04 km/s and a standard $_{416}$ deviation of 0.78 km/s that is 5.6 times larger than the $_{417}$ average RV uncertainty.

Given that the standard deviation of RVs is ~0.8 km/s in IC 2391 and ~0.6 km/s in IC 2602, we confirm that the standard deviations in these clusters is < 1 km/s (Stauffer et al. 1997) and our results are in keeping with the claim that older clusters have larger RV dispersions (Hayes & Friel 2014). For the cluster properties we measure (with the exception of metallicity), standard deviations are larger than both ensemble and mean individual uncertainties. This implies that the observed spread in cluster properties is real and not an artifact of measurement errors. Values are assembled in Table 2.

7. SUMMARY

We use *Gaia* DR2 positions, space motions, and photometry to map out the stellar populations of IC 2602 and IC 2391. Using CHIRON spectra and Empirical SpecMatch, we determine stellar properties and measure signatures of youth for 38 stars. On the basis of this analysis, we obtain the following main results:

We refine the single-star main sequences of IC 2602 (451 stars) and IC 2391 (350 stars). We find a large population of new candidate cluster members (331 stars in IC 2602, 198 stars in IC 2391), never reported before in the literature. The refined membership lists are useful for calibrating models of stellar evolution, planet formation and migration.

- We identify new candidate photometric (4 stars) and spectroscopic (10 stars) binaries; 6 of the latter are single-lined while 4 are double-lined. These findings can be used to improve binary fraction estimates in these clusters. If follow-up observations reveal them to be eclipsing binaries as well, the data can be used to improve stellar evolution models and relations.
- We determine radial and projected rotational velocities, equivalent widths of lithium and ${\rm H}\alpha$, effective temperatures, surface gravities, and metallicities for all 38 stars observed. We confirm that 13 IC 2602 and 12 IC 2391 new candidate members are bona-fide cluster members. This increases the known stellar populations of these clusters (120 stars in IC 2602; 152 stars in IC 2391) by 12% and 8% respectively.
- The data enable new, more precise ensemble stellar properties (Table 2).

8. ACKNOWLEDGMENTS

We are indebted to members of the SMARTS Consortium and NSF's National Optical-Infrared Astronomy Research Laboratory, especially the staff at CTIO,
for efforts to keep the SMARTS/CTIO 1.5-m telescope
and CHIRON spectrograph in operation. We give special thanks to Todd Henry, Wei-Chun Jao, Leonardo
Paredes, Hodari-Sadiki James, Rodrigo Hinjosa, and
Roberto Aviles for scheduling, observing, and reducing
data for stars in the paper. This research has made
use of the SIMBAD database, operated at CDS, Strasbourg, France. This research has made use of the VizieR
catalogue access tool, CDS, Strasbourg, France (DOI
177: 10.26093/cds/vizier). The original description of the
VizieR service was published in 2000, A&AS 143, 23.

Notes. New candidate binaries are indicated as a photometric, b single-lined spectroscopic, or c double-lined spectroscopic. Stars flagged as candidate double-lined spectroscopic binaries have diminished equivalent widths and SpecMatch properties so those measurements are suspect in the table. 12 Nisak et al.
